Early weaning

- Atlantic halibut are fed Artemia until 50-60 dpff, time for developed functional stomach.
- Formulated diets would ease larval rearing.

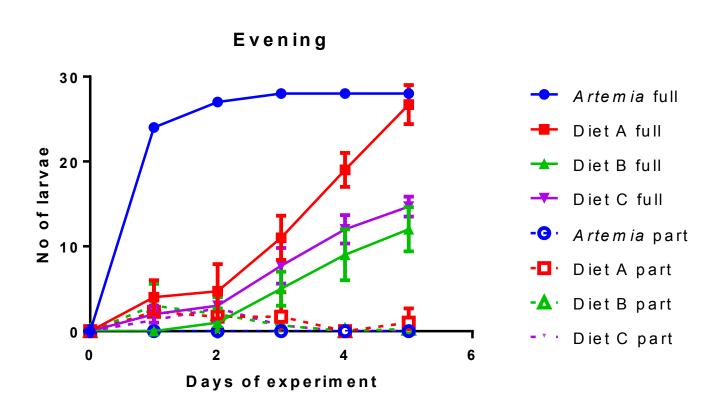

Test of different diets for early weaning

- The diets were fed for 5 days starting at 28 dpff
- Continuous belt feeding and hand feeding morning, midday and evening
- Triplicate 50L tanks with 25-30 larvae initially
- Larvae with filled guts were counted morning and evening using a strong flashlight

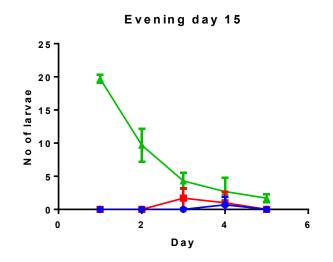

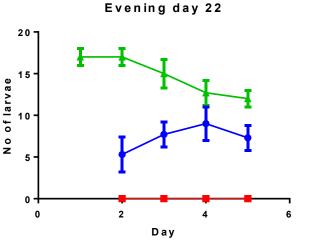

Effect of feeding three different commercial diets to 28dpff Atlantic halibut

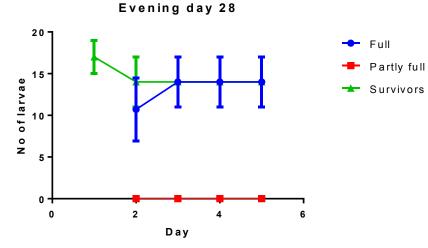

Effect of weaning Atlantic halibut with diet A at 15, 22 or 28 dpff

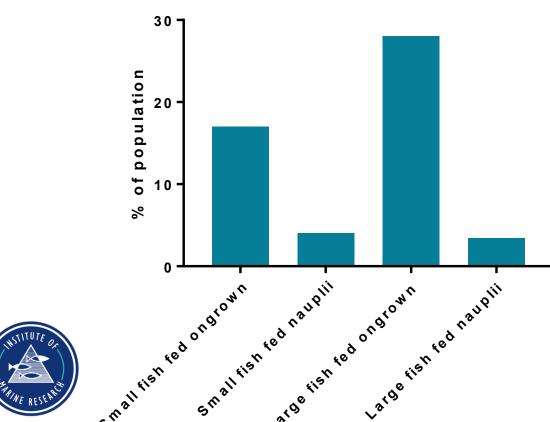

- Development of the digestive tract?
- Coping with the tank system?

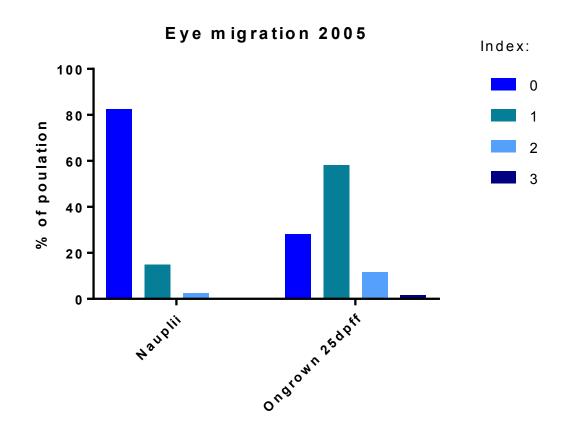

Ongrown Artemia has been shown to improve juvenile quality in halibut

Olsen et al., 1999:

% perfect metamorphosis

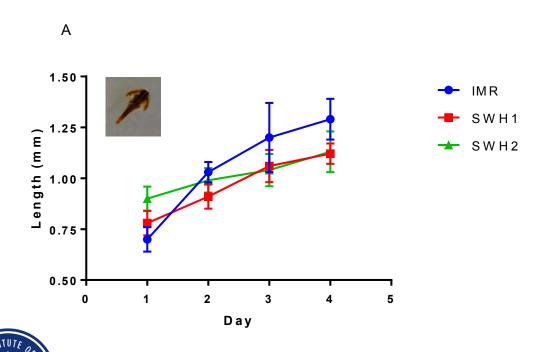

Harboe and Hamre unpublished:

Growth and change in nutrient composition of Artemia

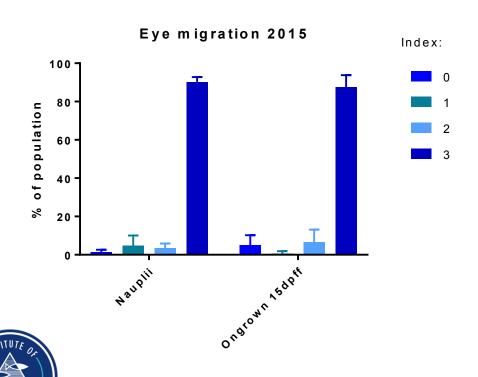

Lengthwise growth of Artemia

Feed: OriGreen or OriGo

- Improvements in nutrient composition:
 - More protein
 - Less lipid
 - Less glycogen
 - More free amino acids
 - More phospholipids
 - Minor changes in vitamins and minerals

Effect of ongrown Artemia on juvenile quality of Atlantic halibut

Conclusion

 Modern diets and rearingmethods for Atlantic halibut make Artemia nauplii a nutritionally sufficient larval diet

Symmetrical larva Pre-metamorphic larva Pro-metamorphic larva Metamorphic climax larva Post-metamorphic juvenile

Tilting, light and vitamin A drives pigmentation and Eye migration in flatfish

- The fish tilts increasingly during metamorphosis
- A gradient of light falls on the skin of the fish
- Generates a gradient of retinoic acid
- Gives direction of eye migration
- Gives signals to melaocytes to produce melanine

Retinoic acid

Entire eye migrates past the dorsal midline Pigment patches

DAH

Upper edge of the migrating eye beyond the dorsal margin

Pigment patches

Swimming in the water column

Lightly pigmented

Prior to eye migration Increasing pigmentation

Eye begins to migrate

Increasing right-side

pigmentation

on both sides

Rhodopsin-Retinal

Shao et al., 2017

Vitamin A is a morphogen

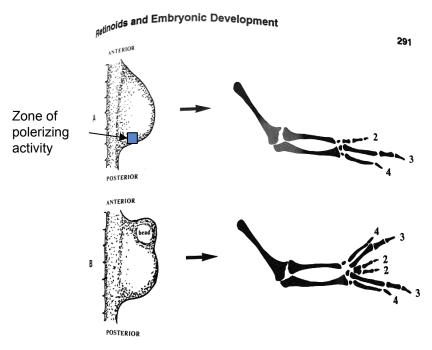

Figure 1 Effects of RA on the chick limb bud. (A) A stage 21 chick limb bud is drawn with its anterior and posterior margins marked which gives rise to a normal three-digit limb. The digits are numbered 2, 3, and 4. (B) After implantation of an RA-soaked bead into the anterior margin of the limb bud a six-digit mirror-imaged limb is produced. The digital sequence of such a limb is 432234. i.e., double posterior.

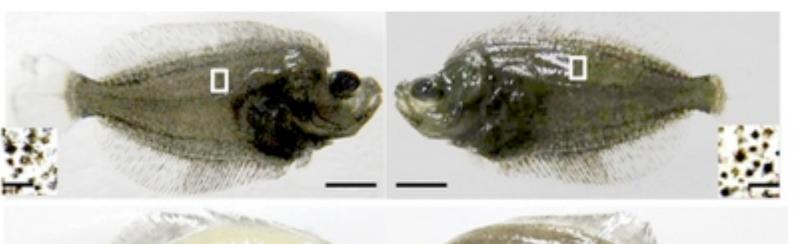

Wikipedia:

A **morphogen** is a substance whose non-uniform distribution governs the <u>pattern</u> of tissue development in the process of <u>morphogenesis</u> or <u>pattern formation</u>, one of the core processes of <u>developmental biology</u>, establishing positions of the various specialized cell types within a tissue. More specifically, a morphogen is a signaling molecule that acts directly on cells to produce specific cellular responses depending on its local concentration.

Evidence of mechanism

Blind side Occular side

Blue light or retinoic acid injection on the blind side

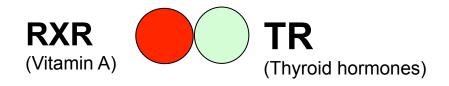

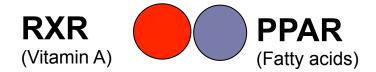

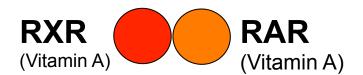

Control

Vitamin A interacts with thyroid hormones and fatty acids through nuclear receptors

The heterodimers of nuclear receptors control gene expression

Vitamin A deficiency

To avoid malformation

- No light from tank walls or bottom
- 2. Sufficient amount of vitamin A (Too much vitamin A gives skeletal deformities)
- 3. There is sufficient cantaxanthin in Artemia to cover vitamin A requirement in halibut larvae
 - Sufficient general nutritionBest hatchery practice
